

METHOD OVERRIDING

In Java, method overriding allows a subclass to provide its own implementation of a method that is already defined in its superclass. This allows the subclass to modify the behavior of the inherited method according to its specific requirements. Method overriding is a fundamental concept in object-oriented programming and promotes code reusability and polymorphism.

Here's an example program that demonstrates method overriding in Java:

```
// Superclass
```

```
class Animal {  
  
    public void makeSound() {  
  
        System.out.println("The animal makes a sound");  
  
    }  
  
}
```

```
// Subclass
```

```
class Cat extends Animal {  
  
    @Override  
  
    public void makeSound() {  
  
        System.out.println("Meow");  
  
    }  
  
}
```

```
// Subclass
```

```
class Dog extends Animal {  
  
    @Override  
  
    public void makeSound() {  
  
        System.out.println("Woof");  
  
    }  
  
}
```

```
    }  
}  
  
// Main class  
  
public class Main {  
  
    public static void main(String[] args) {  
  
        Animal animal = new Animal();  
  
        Cat cat = new Cat();  
  
        Dog dog = new Dog();  
  
        animal.makeSound(); // Output: The animal makes a sound  
  
        cat.makeSound();    // Output: Meow  
  
        dog.makeSound();    // Output: Woof  
  
    }  
  
}
```

In this example, we have a superclass called `Animal` with a method `makeSound()`. The `Cat` and `Dog` classes are subclasses of `Animal` that override the `makeSound()` method with their own implementations.

When we create an object of each class and invoke the `makeSound()` method, the respective overridden method in the subclass is called, producing the desired output.

Note the use of the `@Override` annotation before the `makeSound()` methods in the subclasses. This annotation is optional but recommended as it helps catch errors at compile-time if the method doesn't actually override a method in the superclass.
