

12. MULTIPLICATION OF LARGE INTEGERS

Some applications like modern cryptography require manipulation of integers that are over 100 decimal digits long. Since such integers are too long to fit in a single word of a modern computer, they require special treatment.

In the conventional pen-and-pencil algorithm for multiplying two n -digit integers, each of the n digits of the first number is multiplied by each of the n digits of the second number for the total of n^2 digit multiplications.

The divide-and-conquer method does the above multiplication in less than n^2 digit multiplications.

Example:

$$\begin{aligned}
 23 * 14 &= (2 \cdot 10^1 + 3 \cdot 10^0) * (1 \cdot 10^1 + 4 \cdot 10^0) \\
 &= (2 * 1)10^2 + (2 * 4 + 3 * 1)10^1 + (3 * 4)10^0 \\
 &= 2 \cdot 10^2 + 11 \cdot 10^1 + 12 \cdot 10^0 \\
 &= 3 \cdot 10^2 + 2 \cdot 10^1 + 2 \cdot 10^0 \\
 &= 322
 \end{aligned}$$

The term $(2*1+3*4)$ computed as $2*4+3*1=(2+3)*(1+4)-(2*1)-(3*4)$. Here $(2*1)$ and $(3*4)$ are already computed used. So only one multiplication only we have to do.

For any pair of two-digit numbers $a = a_1a_0$ and $b = b_1b_0$, their product c can be computed by the formula $c = a * b = c_210^2 + c_110^1 + c_0$,

where

$c_2 = a_1 * b_1$ is the product of their first digits,

$c_0 = a_0 * b_0$ is the product of their second digits,

$c_1 = (a_1 + a_0) * (b_1 + b_0) - (c_2 + c_0)$ is the product of the sum of the

a 's digits and the sum of the b 's digits minus the sum of c_2 and c_0 .

Now we apply this trick to multiplying two n -digit integers a and b where n is a positive even number. Let us divide both numbers in the middle to take advantage of the divide-and-conquer technique.

We denote the first half of the a 's digits by a_1 and the second half by a_0 ; for b , the notations are b_1 and b_0 , respectively. In these notations, $a = a_1a_0$ implies that $a = a_110^{n/2} + a_0$ and $b = b_1b_0$ implies that $b = b_110^{n/2} + b_0$. Therefore, taking advantage of the same trick we used for two-digit numbers, we get

$$\begin{aligned} C &= a * b = (a_110^{n/2} + a_0) * (b_110^{n/2} + b_0) \\ &= (a_1 * b_1)10^n + (a_1 * b_0 + a_0 * b_1)10^{n/2} + (a_0 * b_0) \\ &= c_210^n + c_110^{n/2} + c_0, \end{aligned}$$

where

$c_2 = a_1 * b_1$ is the product of their first halves,

$c_0 = a_0 * b_0$ is the product of their second halves,

$$c_1 = (a_1 + a_0) * (b_1 + b_0) - (c_2 + c_0)$$

If $n/2$ is even, we can apply the same method for computing the products c_2 , c_0 , and c_1 . Thus, if n is a power of 2, we have a recursive algorithm for computing the product of two n -digit integers. In its pure form, the recursion is stopped when n becomes 1. It can also be stopped when we deem n small enough to multiply the numbers of that size directly.

The multiplication of n -digit numbers requires three multiplications of $n/2$ -digit numbers, the recurrence for the number of multiplications $M(n)$ is $M(n) = 3M(n/2)$ for $n > 1$, $M(1) = 1$. Solving it by backward substitutions for $n = 2^k$ yields

$$\begin{aligned} M(2^k) &= 3M(2^{k-1}) \\ &= 3[3M(2^{k-2})] \end{aligned}$$

$$\begin{aligned}
 &= 3^2 M(2^{k-2}) \\
 &= \dots \\
 &= 3^i M(2^{k-i}) \\
 &= \dots \\
 &= 3^k M(2^{k-k}) \\
 &= 3^k.
 \end{aligned}$$

(Since $k = \log_2 n$)

$$M(n) \cong 3^{\log_2 n} = n^{\log 3} \approx n^{1.585}.$$

(On the last step, we took advantage of the following property of logarithms: $a^{\log c} = c^{\log a}$.)

Let $A(n)$ be the number of digit additions and subtractions executed by the above algorithm in multiplying two n -digit decimal integers. Besides $3A(n/2)$ of these operations needed to compute the three products of $n/2$ -digit numbers, the above formulas require five additions and one subtraction. Hence, we have the recurrence

$$A(n) = 3 \cdot A(n/2) + cn \text{ for } n > 1, A(1) = 1.$$

By using Master Theorem, we obtain $A(n) \in \Theta(n^{\log_2 3})$,

which means that the total number of additions and subtractions have the same asymptotic order of growth as the number of multiplications.

Example: For instance: $a = 2345$, $b = 6137$,

i.e., $n=4$. Then $C = a * b =$

$$(23 * 10^2 + 45) * (61 * 10^2 + 37)$$

$$C = a * b = (a_1 10^{n/2} + a_0) * (b_1 10^{n/2} + b_0)$$

$$= (a_1 * b_1) 10^n + (a_1 * b_0 + a_0 * b_1) 10^{n/2} + (a_0 * b_0)$$

$$= (23 * 61) 10^4 + (23 * 37 + 45 * 61) 10^2 + (45 * 37)$$

$$= 1403 \cdot 10^4 + 3596 \cdot 10^2 + 1665$$

$$= 14391265$$

STRASSEN'S MATRIX MULTIPLICATION

The Strassen's Matrix Multiplication find the product C of two 2×2 matrices A and B

$$\begin{bmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{bmatrix} = \begin{bmatrix} a_{00} & a_{01} \\ a_{10} & a_{11} \end{bmatrix} * \begin{bmatrix} b_{00} & b_{01} \\ b_{10} & b_{11} \end{bmatrix}$$

$$= \begin{bmatrix} m_1 + m_4 - m_5 + m_7 & m_3 + m_5 \\ m_2 + m_4 & m_1 + m_3 - m_2 + m_6 \end{bmatrix}$$

with just seven multiplications as opposed to the eight required by the brute-force algorithm.

where

$$\begin{aligned} m_1 &= (a_{00} + a_{11}) * (b_{00} + b_{11}), \\ m_2 &= (a_{10} + a_{11}) * b_{00}, \\ m_3 &= a_{00} * (b_{01} - b_{11}), \\ m_4 &= a_{11} * (b_{10} - b_{00}), \\ m_5 &= (a_{00} + a_{01}) * b_{11}, \\ m_6 &= (a_{10} - a_{00}) * (b_{00} + b_{01}), \\ m_7 &= (a_{01} - a_{11}) * (b_{10} + b_{11}). \end{aligned}$$

Thus, to multiply two 2×2 matrices, Strassen's algorithm makes 7 multiplications and 18 additions/subtractions, whereas the brute-force algorithm requires 8 multiplications and 4 additions. These numbers should not lead us to multiplying 2×2 matrices by Strassen's algorithm. Its importance stems from its *asymptotic* superiority as matrix order n goes to infinity.

Let A and B be two $n \times n$ matrices where n is a power of 2. (If n is not a power of

2, matrices can be padded with rows and columns of zeros.) We can divide A , B , and their product C into four $n/2 \times n/2$ submatrices each as follows:

$$\begin{bmatrix} C_{00} & C_{01} \\ C_{10} & C_{11} \end{bmatrix} = \begin{bmatrix} A_{00} & A_{01} \\ A_{10} & A_{11} \end{bmatrix} * \begin{bmatrix} B_{00} & B_{01} \\ B_{10} & B_{11} \end{bmatrix}$$

The value C_{00} can be computed either as $A_{00} * B_{00} + A_{01} * B_{10}$ or as $M_1 + M_4 - M_5 + M_7$ where M_1 , M_4 , M_5 , and M_7 are found by Strassen's formulas, with the numbers replaced by the corresponding submatrices. The seven products of $n/2 \times n/2$ matrices are computed recursively by Strassen's matrix multiplication algorithm.

The asymptotic efficiency of Strassen's matrix multiplication algorithm

If $M(n)$ is the number of multiplications made by Strassen's algorithm in multiplying two $n \times n$ matrices, where n is a power of 2, The recurrence relation is $M(n) = 7M(n/2)$ for $n > 1$, $M(1)=1$.

Since $n = 2^k$,

$$\begin{aligned} M(2^k) &= 7M(2^{k-1}) \\ &= 7[7M(2^{k-2})] \\ &= 7^2M(2^{k-2}) \\ &= \dots \\ &= 7^iM(2^{k-i}) \\ &= \dots \end{aligned}$$

$$= 7^k M(2^{k-k}) = 7^k M(2^0) = 7^k M(1) = 7^k (1) \quad (\text{Since } M(1)=1)$$

$$M(2^k) = 7^k.$$

Since $k = \log_2 n$,

$$M(n) = 7^{\log_2 n}$$

$$= n^{\log_2 7}$$

$$\approx n^{2.807}$$

which is smaller than n^3 required by the brute-force algorithm.

Since this savings in the number of multiplications was achieved at the expense of making extra additions, we must check the number of additions $A(n)$ made by Strassen's algorithm. To multiply two matrices of order $n > 1$, the algorithm needs to multiply seven matrices of order $n/2$ and make 18 additions/subtractions of matrices of size $n/2$; when $n = 1$, no additions are made since two numbers are simply multiplied. These observations yield the following recurrence relation:

$$A(n) = 7A(n/2) + 18(n/2)^2 \text{ for } n > 1, A(1) = 0.$$

By closed-form solution to this recurrence and the Master Theorem, $A(n) \in \Theta(n^{\log_2 7})$. which is a

better efficiency class than $\Theta(n^3)$ of the brute-force method.

Example: Multiply the following two matrices by Strassen's matrix multiplication algorithm.

$$A = \begin{bmatrix} 1 & 0 & 2 & 1 \\ 0 & 1 & 3 & 0 \\ 5 & 0 & 2 & 1 \end{bmatrix} \quad B = \begin{bmatrix} 0 & 1 & 0 & 1 \\ 2 & 1 & 0 & 4 \\ 2 & 0 & 1 & 1 \\ 1 & 3 & 5 & 0 \end{bmatrix}$$

Answer:

$$C = \begin{bmatrix} C_{00} & C_{01} \\ C_{10} & C_{11} \end{bmatrix} \quad A = \begin{bmatrix} A_{00} & A_{01} \\ A_{10} & A_{11} \end{bmatrix} \quad B = \begin{bmatrix} B_{00} & B_{01} \\ B_{10} & B_{11} \end{bmatrix}$$

$$\text{Where } A_{00} = \begin{bmatrix} 1 & 0 \\ 4 & 1 \end{bmatrix}, \quad A_{01} = \begin{bmatrix} 2 & 1 \\ 1 & 0 \end{bmatrix}, \quad A_{10} = \begin{bmatrix} 0 & 1 \\ 5 & 0 \end{bmatrix}, \quad A_{11} = \begin{bmatrix} 3 & 0 \\ 2 & 1 \end{bmatrix}$$

$$B_{00} = \begin{bmatrix} 0 & 1 \\ 2 & 1 \end{bmatrix}, \quad B_{01} = \begin{bmatrix} 0 & 1 \\ 0 & 4 \end{bmatrix}, \quad B_{10} = \begin{bmatrix} 2 & 0 \\ 1 & 3 \end{bmatrix}, \quad B_{11} = \begin{bmatrix} 1 & 1 \\ 5 & 0 \end{bmatrix}$$

$$M_1 = (A_{00} + A_{11}) * (B_{00} + B_{11}) = \begin{bmatrix} 1 & 0 \\ 4 & 1 \end{bmatrix} + \begin{bmatrix} 3 & 0 \\ 2 & 1 \end{bmatrix} * \left(\begin{bmatrix} 0 & 1 \\ 2 & 1 \end{bmatrix} + \begin{bmatrix} 1 & 1 \\ 5 & 0 \end{bmatrix} \right) = \begin{bmatrix} 4 & 0 \\ 6 & 2 \end{bmatrix} * \begin{bmatrix} 1 & 2 \\ 7 & 1 \end{bmatrix} = \begin{bmatrix} 4 & 8 \\ 20 & 14 \end{bmatrix}$$

Similarly apply Strassen's matrix multiplication algorithm to find the following.

$$M_2 = \begin{bmatrix} 4 & 1 \\ 2 & 8 \end{bmatrix}, M_3 = \begin{bmatrix} -1 & 0 \\ -9 & 4 \end{bmatrix}, M_4 = \begin{bmatrix} 0 & -1 \\ 3 & 0 \end{bmatrix}, M_5 = \begin{bmatrix} 0 & 0 \\ 10 & 5 \end{bmatrix}, M_6 = \begin{bmatrix} 4 & -1 \\ -2 & -3 \end{bmatrix}, M_7 = \begin{bmatrix} 0 & 4 \\ -9 & -4 \end{bmatrix}$$

$$C_{00} = \begin{bmatrix} 5 & 4 \\ 4 & 5 \end{bmatrix}, C_{01} = \begin{bmatrix} -7 & 3 \\ 1 & 9 \end{bmatrix}, C_{10} = \begin{bmatrix} 8 & 1 \\ 5 & 8 \end{bmatrix}, C_{11} = \begin{bmatrix} 3 & 7 \\ 7 & 7 \end{bmatrix}$$

$$5 \quad 4 \quad 7 \quad 3$$

$$C = \begin{bmatrix} C_{00} & C_{01} \\ C_{10} & C_{11} \end{bmatrix} = \begin{bmatrix} 4 & 5 & 1 & 9 \\ 8 & 1 & 3 & 7 \\ 5 & 8 & 7 & 7 \end{bmatrix}$$
